HSS 611 - Week 14: Text-as-data

2023-11-27

Agenda

- Pattern matching with regex
 - Introduction to key approaches
- Text normalization
 - Tokenization
 - Stopwords
 - Lemmatization/stemming
- Representing and comparing texts
 - Count vectors
 - TF-IDF
 - Cosine similarity
- Word embeddings
 - Vector semantics
 - Pretrained embeddings

Matching substrings

• Finding and counting substrings

```
print("strawberry".find("berry"))
print("strawberry".count("berry"))
```

5

1

Matching substrings

- Finding and counting substrings
- find() returns -1 for non-match

```
print("strawberry".find("better"))
print("strawberry".count("better"))
-1
```

Matching substrings

Returns the first match

```
print("berryberrystrawberry".find("berry"))
```

C

Matching substrings

• List of 80 fruits

```
import pandas as pd
url = 'https://raw.githubusercontent.com/taegyoon-kim/programming_dhcss_23fw/ma
fruit = pd.read_csv(url, header = None)[0].to_list()
print(len(fruit))
print(fruit[0])
```

80 apple

Matching substrings

Use list comprehension to extract matches

```
[i for i in fruit if i.find("berry") > -1]
['bilberry',
 'blackberry',
 'blueberry',
 'boysenberry',
 'cloudberry',
 'cranberry',
 'elderberry',
 'goji berry',
 'gooseberry',
 'huckleberry',
 'mulberry',
 'raspberry',
 'salal berry',
 'strawberry']
```

What is regex?

- A sequence of characters that forms a flexible search pattern
- Can be used to check if a string contains the specified search pattern

```
import re
mo = re.search(r'berry', 'strawberry.')
print(type(mo))
```

```
<class 're.Match'>
```

Extraction into a list

```
print(mo)
print(mo.group())

berries = [i for i in fruit if re.search(r'berry',i)]
print(berries)

c = re.compile(r'berry') # *compile* the pattern into an object
berries = [i for i in fruit if c.search(i)]
```

```
<re.Match object; span=(5, 10), match='berry'>
berry
['bilberry', 'blackberry', 'blueberry', 'boysenberry', 'cloudberry', 'cranberry')
```

Multiple matches

```
mo_m = re.search(r'berry', "berryberrystrawberry")
print(mo_m.group()) # returns the first match

mo_m2 = re.findall(r'berry', "berryberrystrawberry")
print(mo_m2) # this is a list of strings
```

```
berry
['berry', 'berry', 'berry']
```

Square brackets for "or"

- Square brackets for "or": matches "any one of" the characters in [].
- Read data first

```
url = 'https://raw.githubusercontent.com/taegyoon-kim/programming_dhcss_23fw/ma
sentences = pd.read_csv(url, header = None, sep = '@')[0].to_list()
print(len(sentences))
print(sentences[0])
```

720

The birch canoe slid on the smooth planks.

Square brackets for "or"

• For beat, heat, peat

```
c = re.compile(r' [bhp]eat ')
l_mo = [i for i in sentences if c.search(i)]
for i in l_mo:
    print(i)
```

The heart beat strongly and with firm strokes. Burn peat after the logs give out. Feel the heat of the weak dying flame. A speedy man can beat this track mark. Even the worst will beat his low score. It takes heat to bring out the odor.

Square brackets for "or"

Use – to indicate a range of contiguous characters

```
c = re.compile(r' [b-p]eat ')
l_mo = [i for i in sentences if c.search(i)]
for i in l_mo:
    print(i)
```

The heart beat strongly and with firm strokes. Burn peat after the logs give out.

Feel the heat of the weak dying flame.

A speedy man can beat this track mark.

Even the worst will beat his low score.

Pack the records in a neat thin case.

It takes heat to bring out the odor.

A clean neck means a neat collar.

Square brackets for "or"

 Match anything but one of the characters in the square brackets

```
c = re.compile(r' [^bhp]eat ')
l_mo = [i for i in sentences if c.search(i)]
for i in l_mo:
    print(i)
```

Pack the records in a neat thin case.

A clean neck means a neat collar.

"Or" over multi-character patterns

- We can use | operator
- Parentheses can be used to indicate parts in the pattern

```
c = re.compile(r'(black|blue|red)(currant|berry)')
l_mo = [i for i in fruit if c.search(i)]
l_mo
```

```
['blackberry', 'blackcurrant', 'blueberry', 'redcurrant']
```

The group() attribute

```
c = re.compile(r'(black|blue|red)(currant|berry)')
mo = c.search('blackberry')
print(mo.group(0))
print(mo.group(1))
print(mo.group(2))
```

blackberry black berry

Special characters and the backslash

• Let's create a random example string

eg_str = 'Example STRING, with numbers (12, 15 and also 10.2)?! Wow, two sentences.'

Special characters and the backslash

- There are several characters that have a special meaning in regex, and (may) have to be escaped in order to match the literal character
- They include ^, \$, ., *, +, |, !, ?, (,), [,], {, }, <, and >

Special characters and the backslash

For example, . means "any character but a newline"

```
allchars = re.findall(r'.', eg_str)
print(allchars)

['E', 'x', 'a', 'm', 'p', 'l', 'e', '', 'S', 'T', 'R', 'I
allperiods = re.findall(r'\.', eg_str)
print(allperiods)
```

```
['.', '.']
```

Special characters and the backslash

• For example, . means "any character but a newline"

```
matches = re.findall(r'a.', eg_str)
print(matches)
matches = re.findall(r'a\.', eg_str)
print(matches)
```

```
['am', 'an', 'al']
```

Class shorthands

- "\w" (any alphanumeric character), "\s" (any space character), and "\d" (any numeric digit)
- The capitalized versions of these are used to mean "anything but" that class

```
# any alphanumeric character
matches = re.findall(r'\w',eg_str)
print(matches)

# any non-alphanumeric character
matches = re.findall(r'\W',eg_str)
print(matches)
```

Class shorthands

```
# any whitespace character
matches = re.findall(r'\s', eg_str)
print(matches)

# any non-whitespace character
matches = re.findall(r'\S', eg_str)
print(matches)
```

```
['','','','','','','','','','','']
['E', 'x', 'a', 'm', 'p', 'l', 'e', 'S', 'T', 'R', 'I', 'N', 'G', ',', 'w', 'i', 't', 'h', 'n', 'u', 'm',
```

Class shorthands

```
# any digit character
matches = re.findall(r'\d', eg_str)
print(matches)

# any non-digit character
matches = re.findall(r'\D', eg_str)
print(matches)
```

```
['1', '2', '1', '5', '1', '0', '2']
['E', 'x', 'a', 'm', 'p', 'l', 'e', ' ', 'S', 'T', 'R', 'I', 'N', 'G', ',', ' ', 'w', 'i', 't', 'h', ' ',
```

Quantifiers: * (zero or more of the previous)

```
# any string of zero or more digits
matches = re.findall('\d*', eg_str)
print(matches)
```

Quantifiers: + (one or more of the previous)

```
{\tt matches} = {\tt re.findall('\d+'}, {\tt eg\_str}) # any string of zero or more digits print(matches)
```

```
['12', '15', '10', '2']
```

```
Quantifiers: \{n\} \{n,m\} and \{n,\}
```

- {n} = "exactly n" of the previous
- $\{n,m\}$ = "between n and m" of the previous
- {n,} = "n or more" of the previous

```
Quantifiers: \{n\} \{n,m\} and \{n,\}
```

```
# 3 x's
matches = re.findall(r'x{3}','x xx xxx xxxx xxxx')
print(matches)

# 3 or 4 x's
matches = re.findall(r'x{3,4}','x xx xxx xxxx xxxx')
print(matches)

# 3 or more x's
matches = re.findall(r'x{3,}','x xx xxx xxxx xxxx')
print(matches)
```

```
['xxx', 'xxx', 'xxx']
['xxx', 'xxxx', 'xxxx']
['xxx', 'xxxx', 'xxxxx']
```

```
Quantifiers: ? (zero or one of the previous)

c = re.compile(r' [bp]?eat ')

matches = [i for i in sentences if c.search(i)]

matches

['The heart beat strongly and with firm strokes.',

'Burn peat after the logs give out.',

'A speedy man can beat this track mark.',

'Even the worst will beat his low score.',

'Quench your thirst, then eat the crackers.']
```

Quantifiers

- .+ is a greedy quantifier that matches one or more of any character as many times as possible
- .+? is a non-greedy quantifier that matches as few characters as possible

```
matches = re.findall(r'\(.+\)',
'(First bracketed statement) Other text (Second bracketed statement)')
print(matches)
```

['(First bracketed statement) Other text (Second bracketed statement)']

Quantifiers

- .+ is a greedy quantifier that matches one or more of any character as many times as possible
- .+? is a non-greedy quantifier that matches as few characters as possible

```
matches = re.findall(r'\(.+?\)',
'(First bracketed statement) Other text (Second bracketed statement)')
print(matches)
```

```
['(First bracketed statement)', '(Second bracketed statement)']
```

Quantifiers

- .+ is a greedy quantifier that matches one or more of any character as many times as possible
- .+? is a non-greedy quantifier that matches as few characters as possible

```
matches = re.findall(r'x.+x','x xx xxx xxxx xxxxx')
print(matches)

matches = re.findall(r'x.+?x','x xx xxx xxxx xxxxx')
print(matches)
```

```
['x xx xxx xxxx xxxxx']
['x x', 'x x', 'xx x', 'xxx', 'xxx']
```

Caveat

- The objective of text normalization is to clean up text and transform it into meaningful units of analysis
- A specific combination of techniques to be employed is highly dependent on your research question
- You always need to ask yourself what impact your decisions would have on subsequent analyses

Caveat

Text Preprocessing For Unsupervised Learning: Why It Matters, When It Misleads, And What To Do About It

Matthew J. Denny¹ and Arthur Spirling²

¹ 203 Pond Lab, Pennsylvania State University, University Park, PA 16802, USA. Email: mdenny@psu.edu
² Office 405, 19 West 4th St., New York University, New York, NY 10012, USA. Email: arthur.spirling@nyu.edu

Abstract

Despite the popularity of unsupervised techniques for political science text-as-data research, the importance and implications of preprocessing decisions in this domain have received scant systematic attention. Yet, as we show, such decisions have profound effects on the results of real models for real data. We argue that substantive theory is typically too vague to be of use for feature selection, and that the supervised literature is not necessarily a helpful source of advice. To all dresearchers working in unsupervised settings, we introduce a statistical procedure and software that examines the sensitivity of findings under alternate preprocessing regimes. This approach complements a researcher's substantive understanding of a problem by providing a characterization of the variability changes in preprocessing choices may induce when analyzing a particular dataset. In making scholars aware of the degree to which their results are likely to be sensitive to their preprocessing decisions, it also replication efforts.

Keywords: statistical analysis of texts, unsupervised learning, descriptive statistics

Tokenization

- A token is an instance of a sequence of characters in a document that are grouped together as a useful semantic unit
- Tokenization is the task of segmenting running text into tokens
- The very start of downstream NLP tasks
- NLTK (Natural Language ToolKit), among many others, offers useful tools for tokenization

Import NLTK and Punkt Tokenizer

- There are a wide range of tokenizers
- They differ in various aspects
 - E.g., handling punctuation, special characters, or numbers
- See the official document of Punkt Tokenizer

```
import nltk
#nltk.download('punkt') # import Punkt Tokenizer
from nltk.tokenize import sent_tokenize
from nltk.tokenize import word_tokenize
```

 ${\tt text} = {\tt ""Altman}$ announced a few weeks ago at OpenAI's first-ever developer day that the company would main print(text)

Altman announced a few weeks ago at OpenAI's first-ever developer day that the company would make tools a OpenAI has also worked with Microsoft to roll out ChatGPT-like technology across Microsoft's products. OpenAI and iPhone designer Jony Ive had also reportedly been in talks to raise \$1 billion from Japanese c

```
sentences = sent_tokenize(text) # a.k.a sentence segmentation
for s in sentences:
    print(f"{s}\n")
```

Altman announced a few weeks ago at OpenAI's first-ever developer day that the company would make tools a

 ${\tt OpenAI \ has \ also \ worked \ with \ Microsoft \ to \ roll \ out \ ChatGPT-like \ technology \ across \ Microsoft's \ products.}$

OpenAI and iPhone designer Jony Ive had also reportedly been in talks to raise \$1 billion from Japanese c

```
tokenized = word_tokenize(sentences[1])
for i in tokenized:
    print(i)

OpenAI
has
also
```

```
has also worked with Microsoft to roll out ChatGPT-like technology across Microsoft , s products
```

Stop words

- Stop words are the words that are filtered out (due to insignificance)
- For the previous example, the words like 'the' or 'an' are not quite meaningful
- Again, however, it depends upon the nature of the task you are working on
- E.g., topic modeling vs. language modeling

Stop words

```
from nltk.corpus import stopwords
#nltk.download('stopwords')
print(len(stopwords.words('english')))
print(stopwords.words('english')[0:10])
```

```
179
['i', 'me', 'my', 'myself', 'we', 'our', 'ours', 'ourselves', 'you', "you're"]
```

Stop words

```
tokens = word_tokenize(sentences[1])

tokens_no_sw = [t for t in tokens if not t.lower() in stopwords.words('english')]

print(tokens)
print(tokens_no_sw)
```

```
['OpenAI', 'has', 'also', 'worked', 'with', 'Microsoft', 'to', 'roll', 'out', 'ChatGPT-like', 'technology ['OpenAI', 'also', 'worked', 'Microsoft', 'roll', 'ChatGPT-like', 'technology', 'across', 'Microsoft', ''
```

Lemmatization

- Lemmatization is identifying the base form of a word, irrespective of its surface variations
 - 'am', 'are', and 'is' share the same lemma 'be'
 - 'dog', 'dogs', and 'doggy' share the same lemma 'dog'
- Built on morphological parsing (splitting words into morphemes)

Lemmatization

```
from nltk.stem import WordNetLemmatizer
#nltk.download('wordnet')

tokens = ['cats', 'doing', 'lives', 'has',
    'going', 'legislate', 'asocial', 'flew', 'friendly', 'loved']

wordnet_lemmatizer = WordNetLemmatizer()
tokens_lemma = [wordnet_lemmatizer.lemmatize(w) for w in tokens]
print(tokens)
print(tokens_lemma)
```

```
['cats', 'doing', 'lives', 'has', 'going', 'legislate', 'asocial', 'flew', 'friendly', 'loved']
['cat', 'doing', 'life', 'ha', 'going', 'legislate', 'asocial', 'flew', 'friendly', 'loved']
```

Stemming

- Stemming is a simpler but cruder method (lemmatization algorithms are be complex)
- Consists of chopping off word-final affixes
- There are various stemming algorithms as well

Stemming

```
from nltk.stem import PorterStemmer

tokens_stem_p = []

ps = PorterStemmer()
for w in tokens:
    root = ps.stem(w)
    tokens_stem_p.append(root)

print(tokens)
print(tokens_stem_p)
```

```
['cats', 'doing', 'lives', 'has', 'going', 'legislate', 'asocial', 'flew', 'friendly', 'loved']
['cat', 'do', 'live', 'ha', 'go', 'legisl', 'asoci', 'flew', 'friendli', 'love']
```

Stemming

```
from nltk.stem import LancasterStemmer

tokens_stem_l = []

ls = LancasterStemmer()
for w in tokens:
    root = ls.stem(w)
    tokens_stem_l.append(root)

print(tokens)
print(tokens_stem_p)
print(tokens_stem_l)
```

```
['cats', 'doing', 'lives', 'has', 'going', 'legislate', 'asocial', 'flew', 'friendly', 'loved']
['cat', 'do', 'live', 'ha', 'go', 'legisl', 'asoci', 'flew', 'friendli', 'love']
['cat', 'doing', 'liv', 'has', 'going', 'legisl', 'asoc', 'flew', 'friend', 'lov']
```

No single answer to how we should go about this

- It is a good practice to understand what happends under the hood at each step of the process (tokenization -> stop words -> lemmatization/stemming)
- One approach is not only think in advance deductively which combination would be most suitable but also run robustness analyses built on different combinations
- Another (less ideal but easier) approach is to (critically) follow "the norm"

The BoW model (the bag-of-words model)

- The BoW model is a model of text represented as an unordered collection of words
- Converting running text to BoW data in the form of a DTM (document-term matrix)

DTM (document-term matrix)

Count vectors

Document D1	The child makes the dog happy the: 2, dog: 1, makes: 1, child: 1, happy: 1
Document D2	The dog makes the child happy the: 2, child: 1, makes: 1, dog: 1, happy: 1

	child	dog	happy	makes	the	BoW Vector representations
D1	1	1	1	1	2	[1,1,1,1,2]
D2	1	1	1	1	2	[1,1,1,1,2]

Count vectors

- Most easily done in Python with CountVectorizer from the ML library scikit-learn
- We will use the example of U.S. presidents' inaugural speeches

from sklearn.feature extraction.text import CountVectorizer

https://raw.githubusercontent.com/taegyoon-kim/programming_dhcss_23fw/main/week_14/inaugural_speech_u

```
url = 'https://raw.githubusercontent.com/taegyoon-kim/programming_dhcss_23fw/main/week_14/inaugural_speecinaugural_df = pd.read_csv(url)

print(len(inaugural_df)) # 58 speeches/documents
print(inaugural_df.head()) # the first five

58

and a transport of the contract of the contrac

Count vectors

vectorizer = CountVectorizer() # many text normalization decisions here

- No lemmatization/stemming included!
- stop_words = None
- lowercase = True
- max_df, min_df, ngram_range, etc.
- See here for a complete set of arguments

fit_tranform

- fit means learning the vocabulary of from the corpus
- transform means creating a matrix and populating with counts

```
dtm = vectorizer.fit_transform(inaugural_df['text'])
dtm # 58 * 9046 (vocabulary)
```

<58x9046 sparse matrix of type '<class 'numpy.int64'>'
with 43638 stored elements in Compressed Sparse Row format>

Shape and sparsity

```
print(dtm.shape)
print(dtm.size) # non-zero elements

import numpy as np
1 - (float(dtm.size) / np.prod(dtm.shape))

(58, 9046)
43638
0.9168274032340451
```

Inside DTM

```
arr_dtm = dtm.toarray()
print(arr_dtm)

[[0 0 0 ... 0 0 0]
      [0 0 0 ... 0 0 0]
      [0 0 0 ... 0 0 0]
      ...
      [0 0 0 ... 0 0 0]
      [0 0 0 ... 0 0 0]
      [0 0 0 ... 0 0 0]
```

Inside DTM

```
vocab = vectorizer.get_feature_names_out()
print(vocab[0:30])
print(vocab[-10:])

['000' '100' '120' '125' '13' '14th' '15th' '16' '1774' '1776' '1778'
    '1780' '1787' '1789' '1790' '1800' '1801' '1812' '1815' '1816' '1817'

```

TF (Term Frequency) - IDF (Inverse Document Frequency) vectors

- Counter vectors consider the frequencies of words
- However, some words are too frequent: the, a, an, etc.
- We want to weight how unique a word is in the corpus

TF-IDF vectors

$$W_{x,y} = tf_{x,y} \times log(\frac{N}{df_x})$$

TF-IDF

Term x within document y

 $tf_{x,y}$ = frequency of x in y df_x = number of documents containing xN = total number of documents

```
from sklearn.feature_extraction.text import TfidfVectorize:
corpus = ['can you fly', 'can you sleep']
tf_idf_vectorizer = TfidfVectorizer()
tf_idf_matrix = tf_idf_vectorizer.fit_transform(corpus)
```

Let's use news titles data

```
import pandas as pd
```

```
url = 'https://raw.githubusercontent.com/taegyoon-kim/programming_dhcss_23fw/main/week_14/news_title.csv'
news_df = pd.read_csv(url, sep = ';')
news_df = news_df.sample(1000) # random sample of 1,000
```

TF-IDF vectors

Cosine similarity

$$\cos(heta) = rac{\mathbf{A} \cdot \mathbf{B}}{\|\mathbf{A}\| \|\mathbf{B}\|} = rac{\sum\limits_{i=1}^n A_i B_i}{\sqrt{\sum\limits_{i=1}^n A_i^2} \sqrt{\sum\limits_{i=1}^n B_i^2}}$$

• It ranges from -1 (opposite) to 0 (orthogonal) to 1 (identical)

Creating a cosine similarity matrix

```
from sklearn.metrics.pairwise import cosine_similarity

cos_sim_mat = cosine_similarity(tf_idf_df, tf_idf_df)

cos_sim_df = pd.DataFrame(
    cos_sim_mat,
    columns = news_df['No'],
    index = news_df['No'])

cos_sim_df.head()
```

No No	17680	6327	56517	53129	53279	40545	39854	36360	2107
17680	1.000000	0.0	0.0	0.0	0.040762	0.0	0.0	0.0	0.000
6327	0.000000	1.0	0.0	0.0	0.000000	0.0	0.0	0.0	0.000
56517	0.000000	0.0	1.0	0.0	0.000000	0.0	0.0	0.0	0.000
53129	0.000000	0.0	0.0	1.0	0.000000	0.0	0.0	0.0	0.000
53279	0.040762	0.0	0.0	0.0	1.000000	0.0	0.0	0.0	0.022

Representing the matrix as an edge list

```
edges = []
for i in range(len(cos_sim_df)):
    for j in range(i+1, len(cos_sim_df)):
        weight = cos_sim_df.iloc[i, j]
        edges.append((cos_sim_df.index[i], cos_sim_df.columns[j], weight))
edges_df = pd.DataFrame(edges, columns = ["source", "target", "weight"])
edges_df.head()
```

	source	target	weight
0	17680	6327	0.000000
1	17680	56517	0.000000
2	17680	53129	0.000000
3	17680	53279	0.040762
4	17680	40545	0.000000

Add category labels

```
edges_df_m1 = pd.merge(
  edges_df, news_df[['No', 'Category']],
  left_on = 'source',
    right_on = 'No',
    how = 'left')

edges_df_m2 = pd.merge(
  edges_df_m1, news_df[['No', 'Category']],
  left_on = 'target',
    right_on = 'No',
    how = 'left')

edges_df_m2['comb'] = edges_df_m2['Category_x'] + '-' + edges_df_m2['Category_y']
  edges_df_m2['comb']
```

```

                Business-Medical
499499
Name: comb, Length: 499500, dtype: object
```

Average cosine similarity

```
edges_df_m2.groupby('comb')['weight'].agg('mean').sort_values(ascending = False)
```

```
comb

Vector semantics

- Vector semantics starts with learning representations of the meaning of words
- Distributional hypothesis: words that occur in similar contexts tend to have similar meanings (from the 1950s in linguists' work such as Harris 1954)
- The very beginning of vector semantics dates back at least to Osgood et al. (1957) where words were represented in a 3-dimensional vector space (valence, arousal, dominance)

	Valence	Arousal	Dominance
music	7.67	5.57	6.5
heartbreak	2.45	5.65	3.58

What are word embeddings?

- Word embeddings refer to short dense vectors for representing words (Word2vec, BERT, etc.)
- They are used to position a word as a point in a multidimensional semantic space

What are word embeddings?

- A paradigm shift from the traditional BoW approach
- Employ neural networks to learn word representations from a large corpus
- Explicitly considers context (not "contextual embeddings" like BERT though)

What are word embeddings?

- Many useful applications
 - Discover the relationships between words (compute their similarity)
 - Track changes in meaning
 - Other applications like text classification or clustering
- Note that dimensions are not interpretable

Word2Vec

 A set of algorithms (CBOW and SGNS) for learning word representations from a corpus

Pre-trained embeddings
